The authors thank Dr. L. S. Bird, Texas Agricultural Experiment Station, for supplying the starter cultures of the races of Xanthomonas malvacearum used. Evaluation of  $F_3$  and  $F_4$  Lines of Cotton From Crosses of Race Accessions with Upland For Resistance to Bacterial Blight

# Evaluation of F<sub>3</sub> and F<sub>4</sub> Lines of Cotton From Crosses of Race Accessions with Upland for Resistance to Bacterial Blight

Eighty one lines of cotton, ossypium hirsutum L., conining germplasm from 54 rimitive accessions in the race ollection have been released lenkins et al, 1979). The primitive ccessions were originally crossed s males with either 'Deltapine 16' OPL-16) and/or Lubbock Dwarf. he procedure for developing the owering lines and maintaining enetic diversity was presented by IcCarty el al, 1979. Also, sixteen dditional lines with Fusarium rilt resistance have been released Jenkins et al, 1979).

In 1978 and 1979, 82 cotton lines nvolving 54 race accessions, 10  $SC_2F_5$  lines and 119  $F_3$  race nes were evaluated for bacterial light (Xanthomonas nalvacearum (E.F. esistance in greenhouse tests. The acterial blight inoculum consisted f a mixture of Races 1, 2, 7, 10 and 8 in equal volumetric portions. Before mixing each race, inoculum vas standardized to equivalent pacterial density (ca 4 x 10" viable cells/ml) based upon colorimeter eading (Mahill et al, 1978). The experimental designs were randomized complete blocks replicated our times.

The lower epidermis of seedling otyledons was inoculated when nost of the tissues were fully expanded (10-13 days after planting). Speed Ball #B-6 pens with the prongs 1.5 mm apart were used to noculate the cotyledons. Visual elight ratings were recorded following maximum disease reactions, which occurred from nine to 13 lays after inoculation (Mahill et al, 1978). A mean of the blight readings of six to ten plants per centry per replication was used as a disease grade for each experimen-

tal observation. The check cultivars used were 'Deltapine 61,' 'Stoneville 213' and GN-6-76. The disease grading scale is given in

Table 1 (Mahill et al, 1978). Resistant and susceptible extremes of the grading scale are shown in Figure 1.

RESISTANT (Grade 2) ← SUSCEPTIBLE (Grade 9) <

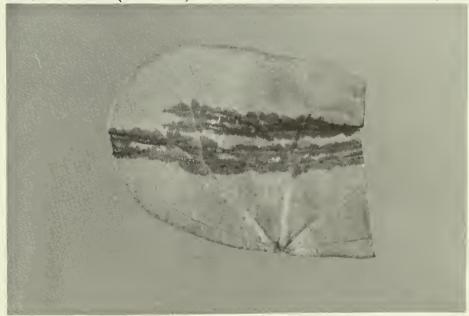

Figure 1. Resistant and susceptible extremes outlined in Table 1.

Resistance Level	Disease Grade	Description of affected tissues
Susceptible	9	Completely susceptible - excessi water soaking of tissue and lesi are spreading.
	8	Solid water soaking of tissue ar spreading well.
	7	Solid water soaking of tissue, definitely outside the scratch marks with little or no spreading
Intermediate	6	Solid water soaking, but only occasional spreading outside the scratch marks.
	5	Water soaking of tissues in the scratch marks.
	4	Very slight signs of water soaki of tissues.
Resistant	3	Tissue darkening with no signs of water-soaked tissue.
	2	Tissue brown with no signs of water-soaked tissue.
	1	Completely resistant - tissue is white or gray resembling scar tissue from the scratch.

Evaluations of the 82  $F_4$  and 10  $BC_2$   $F_5$  cotton lines (Table 2) showed that 11 lines were equal to and 30 lines were non-significantly less susceptible than Stoneville 213. Race stock lines with Lubbock Dwarf as female parent apparently were intermediate while their counterparts with DPL-16 as female parent were susceptible. In the  $F_3$  lines (Table 3), resistance

higher than that of DPL-61 or Stoneville 213 was not observed. In general, the blight grades for all the cotton lines formed a normal distribution around the commercial checks. This distribution indicates that the converted race stock lines of cotton exhibit minor gene effects and are near the same level as the commercial checks. Genes no more effective than the

known minor genes probably are involved. However, it is generally well known that major genes are not effective unless combined with compatible and complementary minor-modifier genes (Bird, L. S. personal communication). The identification of minor-modifie genes could complement known major genes.

The technique of mixed inoculum of X. malvacearum races used in his study was considered to be the eason for no more than intermediate grades. However, the presence of single genes that may be effective against single races of the pathogen cannot be ruled out. The best cotton lines reported therein may exhibit resistance to specific races.

Numerous primitive race accessions from diverse geographic origins were progenitors of the F<sub>3</sub> and F<sub>4</sub> cotton lines evaluated. Most were from Guerrero, Chiapas, and Oaxaco, Mexico, and Guatemala (Table 4). A high percentage of the lines originating from Chiapas and Oaxaca were intermediate in resistance to

bacterial blight. A few lines from Hopi N. Mex. 1239, Hopi Mb-14-1-3, Belize, and from the Bahamas were more resistant than lines from other areas.

Predominately, the cotton lines had latifolium, punctatum, and morrilli race backgrounds (Table 5), and a large number of these were intermediate in resistance. A mean blight grade for morrilli of 6.3 (intermediate resistance) indicated a possible source of resistance in this cotton race.

Resistance to bacterial blight in this study was not associated with any cotton race or geographic origin. An increase in susceptibility over the upland parent apparently occurred in a few of the flowering lines. Cotton breeders should be aware of this response when using these exotic lines.

Our results tend to confirm previous research on bacterial blight (R. L. Knight, et al, 1950). According to Knight, the center of variability for the G. hirsutum species is in Central America. However, both Central and South America were poor areas for isolating cotton lines resistant to blackarm (bacterial blight). New-World strains of punctatum derived from Florida and the Bahamas showed resistance. In the data reported herein, two cotton lines from the Bahamas (Table 4) were intermediate in resistance.

Table 2. Bacterial blight resistance of the  $F_4$  generation of 82 lines of cotton, Gossypium hirsutum L. (containing germplasm from 54 primitive races of cotton), and 10 BC<sub>2</sub>F<sub>5</sub> lines of cotton.

<sup>\*</sup> Significantly more susceptible than ST213.

<sup>1</sup>/ Race designation: 1 = latifolium; 2 = punctatum; 8 = unclassified.

- 2/ Site of original collection of primitive races used in initial
  crosses: 1 = Guerrero, Mex.; 2 Pueblo, Mex.; 3 = Chiapas, Mex.;
  4 = Guatemala; 5 = Oaxaca, Mex.; 6 = El Salvador; 7 = Mexico; 8 =
  Yucatan, Mex.; 9 = Unknown; 10 = Hopi M6-14-1-3; 11 = Hopi N. Mex.
  1239.
- 3/ Individual plants initially graded on a 1-9 scale (Table 1). Any 2 means within an experiment followed by the same letter are not significantly different based on Newman-Keul's test.
- Bacterial blight evaluation rating, R = resistant (1.0-3.4), I = intermediate resistance (3.5-6.4), S = susceptible (6.5-9.0).

Table 4. Bacterial blight resistance of  $F_3$  and  $F_4$  lines, number tested, number grading interemediate resistance, and mean grade, by site of original collection of race accession progenitor.

Site of orginal collection	No. tested	No. graded intermediate	Mean blight grade
Guerrero, Mex.	17	4	6.6
Pueblo, Mex.	2	1	6.3
Chiapas, Mex.	36	18	6.5
Guatemala	65	18	6.6
Oaxaca, Mex.	24	11	6.5
El Salvador	8	1	6.9
Mexico	5	1	6.5
Yucatan, Mex.	2	2	6.4
			(Continued)

Site of orginal collection	No. tested	No. graded intermediate	Mean blight grade
Hopi N. Mex. 1239	3	2	6.2
Hopi Mb-14-1-3	1	1	6.1
Veracruz, Mex.	4	3	6.3
San Luis P. Mex.	3	1	6.7
Belize	7	4	6.2
Bahama Island	2	2	5.9
Unknown	22	11	6.5
TOTAL	201	80
