Preface

Weather and climate influence virtually all phases of production in agriculture and forestry. The climatic data, either basic or derived, needed for decision-making by Mississippi producers are not generally available except in diverse forms and sources. This document compiles into one comprehensive source many of those needed data. Data are presented in tabular and graphical formats covering several aspects of each of the broad areas of moisture, energy, and derived variables. Specific topics for which data are presented include precipitation, temperature, freeze dates, solar radiation, day length, evaporation, DD60's, water temperature, water balance, and crop water demand. Unavailability of wind and relative humidity data, as well as data for short time periods, such as hourly, is discussed.

Acknowledgments

The authors wish to acknowledge the contributions of the following to the preparation of this document:

The Mississippi Agricultural and Forestry Experiment Station and the Departments of Agricultural and Biological Engineering and Geology and Geography, Mississippi State University, for financial support of the State Climatologist program and for funding this project.

Dr. Mark S. Binkley, Director, Climatology Laboratory, Department of Geology and Geography, Mississippi State University; Dr. Thomas A. Monaghan, Extension Leader for Forestry, Mississippi Cooperative Extension Service; and Dr. George P. Mullendore, Coordinator, USDA Cotton Simulation Program, for critical review of the manuscript.

B.J. Whitehead and Pam Shaunak for their courteous help in graphics and typing of the manuscript.

Selected Climatological Features Affecting Agriculture and Forestry in Mississippi

Introduction

The suitability of a region for agricultural and forestry production is strongly influenced by the climatic attributes of the region. Growth of plants in any environment is dependent upon the delivery, by climatic processes, of moisture and energy to the land surface. Virtually all phases of plant and animal life - germination, growth and development, maturity, vield or productivity, reproduction - are influenced to some degree by the environmental factors of weather and climate. Furthermore, both agricultural and silvicultural crops are subject to a wide variety of diseases and insects that are weather and climate dependent. Principal features of climate that establish limits for growth and development of crops and forests are characteristics of moisture, energy, and quantities derived from the interplay of these factors.

Many of the basic and most of the derived climatological variables needed to understand the impact of climate on plant or animal production are not generally available, or are not available in the form required, for Mississippi producers. Mississippi Agricultural and Forestry Experiment Station scientists, the State Climatologist, and Mississippi Cooperative Extension Service specialists often receive requests for such weather and climate information. The purpose of this document is to present selected aspects of climatological data that are available by consolidating a variety of information from a number of different sources. Some of the information is in the form of raw data, some is in the form of derived variables that have been computed, and some is in a form not usually published but for which a demand exists.

Data Sources, Adjustments, and Presentation

Topics selected for presentation fall into one of three categories: (1) moisture—precipitation; (2) energy—temperature, solar radiation, daylength, and evaporation; and (3) derived variables—degree day 60 heat units (DD60's), water temperatures, water balance, and crop water demand. The order of the topics generally follows a progression from those data most available to those data least available.

Some of the features portrayed are simple and re-

quired only that the data be assembled. Others are complex and required multiple procedures to process and make the data available. A variety of tables and figures are used, and several methods were used to correct for missing data or otherwise adjust records to ensure the best possible quality and serial consistency of the data. Details of the methods used to retrieve, correct or adjust, and analyze the data within each topic are included with the data for each topic.

Precipitation

Precipitation data presented are monthly totals observed in each of the 10 climate divisions for the 30-year period 1960-1989. The data are presented in tables and in isohyet maps.

Tables 1-10 include monthly total precipitation from representative climate recording stations within each of the 10 climate divisions in the state. Data were retrieved from CD-ROM based on National Weather Service Cooperative Observation Network records available through Earth Info, Inc. (Climatedata, 1989). Stations were chosen based upon the quality and completeness of the records. Missing data were inserted into the records by using either the divisional average or the measurement from the nearest station for the month in question. Therefore, the data are serially complete and quality controlled and are available in no other published source.

Each table includes monthly and annual totals of precipitation (inches) for each year, average monthly and annual totals of the 30-year period, as well as monthly and annual maximum and minimum amounts recorded. Monthly standard deviations are also included. For example, Table 1 (Climate Division 1, represented by Cleveland, MS) shows that there was a total of 5.83 inches in January 1960, the average monthly amount for 1960 was 4.38 inches, and the maximum and minimum monthly amounts observed in 1960 were 6.47 inches (Dec.) and 2.37 inches (Aug.), respectively. The average for January is 4.42 inches, the maximum for January is 11.54 inches (1974), the minimum for January is 0.38 inch (1986), and the standard deviation for January is 2.72 inches.

These same data are presented in a visual format by mapping the distribution of precipitation across the state for each month and annually (Figures 1-13). This information is a unique addition to the Mississippi climatological literature because, in addition to the 10 locations inside the state, data from ll locations outside but near the state boundaries were similarly retrieved and processed for use in the mapping procedure. This addition of data points outside the state increases the accuracy of the spatial depiction of monthly precipitation by carrying the analysis across the borders and thereby negating the artificial constraints usually associated with such mapping attempts.

Temperature

Daily maximum and minimum temperature data for the period 1951-1980 were retrieved from CD-ROM based on National Weather Service Cooperative Observation Network records available through Earth Info, Inc. (Climatedata, 1989). Stations were chosen from the northern (Water Valley), central (Canton), and southern (Hattiesburg) parts of the state based upon the quality and completeness of the records. Missing data were inserted into the records by using the measurement from the nearest station for the day in question. Therefore, the data are serially complete and quality controlled, and are available in no other published source.

The adjusted daily data were retrieved into Lotus 1-2-3 spreadsheets (Lotus, 1986) and an average value was calculated for each day. These average daily values, maximum and minimum, were graphed to show the annual regimes of temperature at the three locations and to show the spatial differences in temperature across the state through the year (Figures 14, 15, and 16).

Also included (Table 11), are probabilities of the first and last freeze dates and length of the freeze-free period for the same three locations. These data were derived and published for these locations and others in the state by the National Climatic Data Center (1985), and are included here to enhance the understanding of the temperature regime as it impacts agriculture and forestry in the state.

Solar Radiation

The solar radiation data were observed at Delta Branch Experiment Station, Stoneville, MS, and stored in computer files at Mississippi State University. The data were retrieved and formatted into Tables 12-23 to provide daily values by month for the years 1962-1987. The observed values, computed average, maximum value, and minimum value for each day as well as the monthly totals are given in units of calories/square centimeter/day. For example, Table 12 shows that the observed value for January 10, 1970 is 196 cal/sq cm, the 26-year average for January 10 is 210 cal/sq cm, the maximum observed

for that date is 545 cal/sq cm (1962), and the minimum observed for that date is 42 cal/sq cm (1974). The monthly total for January 1970 is 8035 cal/sq cm.

Day Length

The length of daylight in Mississippi is presented in Tables 24-26, as computed from equations found in Duffie and Beckman (1980). Locations in the northern (Water Valley), central (Canton), and southern (Hattiesburg) parts of the state are used to illustrate the varying periods of light (hours) across the state during the year. For example, on January 1, daylength ranges from 9.8 hours in the north (Table 24) to 10.0 hours in the southern (Table 26) part of the state, whereas on June 30, the length of daylight ranges from 14.0 hours in the south (Table 26) to 14.3 hours in the northern (Table 24) part of the state.

Evaporation

Evaporation data were retrieved from CD-ROM, available from the National Weather Service Cooperative Observation System through Earth Info, Inc. (Climatedata, 1989). The data were retrieved into Lotus 1-2-3 spreadsheets (Lotus, 1986) for inspection and quality control. The raw data were serially incomplete and contained obvious errors.

In order to produce a serially complete and more accurate daily evaporation record, the raw data were used to compute an average for each day of the year. The average was then used to fill in missing daily values for every year. These daily values for each year were then graphed on the computer monitor and visually inspected for abnormally high and low points, which were noted and subsequently located in the data files. Adjustments were then made to correct for the identified errors such as accumulated values following a long string of missing observations or typographical mistakes. If the observation in question appeared obviously wrong but no cause was readily evident, the average value for that day was substituted. Less than 4 percent of the observations were adjusted in this manner. The result of this tedious procedure yields a reasonably accurate and complete record of daily pan evaporation.

The adjusted data for Stoneville, MS, were formatted into Tables 27-38 to provide daily values by month for the years 1962-1987. The observed values, computed average, maximum value, and minimum value for each day as well as the monthly totals are given in units of inches/day. For example, Table 27 shows that the observed value for January 10, 1970 is 0.02 inch, the 26-year average for January 10 is 0.03 inch, the maximum observed for that date is 0.13 inch (1984), and the minimum observed for that date is 0.0

inches (observed in 5 years). The monthly total for January 1970 is 0.54 inch.

In order to depict the envaporation gradient from the coastal to the inland parts of the state, data from the nearest sites with complete records (Fairhope, AL and Stuttgart, AR) were similarly processed. These data, along with the data for Stoneville, MS, were then graphed (Figures 17, 18, and 19) to visually show the evaporation regime across the state by comparing the annual patterns of daily maximum, average, and minimum values at the three sites.

Degree Day 60's (DD60's)

A degree day 60 (DD60) is a heat unit derived by calculating a daily mean temperature (°F) and subtracting from that value a base temperature of 60°F. The difference is the number of DD60's for that particular day. DD60's accumulated through a time period become an index to represent the thermal environment and can be used to forecast plant growth and development or heating and cooling requirements.

Daily maximum and minimum temperature data for the period 1951-1980 were retrieved from CD-ROM based on National Weather Service Cooperative Observation Network records available through Earth Info, Inc. (Climatedata, 1989). Stations were chosen based upon the quality and completeness of the records and to represent major agricultural producing areas of the state. Missing data were inserted into the records by using the measurement from the nearest station for the day in question. Therefore the data are serially complete and quality controlled.

Average daily temperatures were computed using the maximum and minimum data. These daily averages were then departed from the 60 °F threshhold to compute the daily heat units, which were then summed by 7-day periods based on standard climatological weeks of the average growing season for Mississippi. Probabilities for accumulation of DD60's for any given week during the growing season were computed by use of empirical quantile methods.

Tables 39-46 present the mean, maximum, and minimum DD60 accumulations as well as the standard deviations and probabilities at 10 levels for each week. For example, Table 39 shows that, for the week beginning May 3, the average weekly DD60 accumulation at Canton, MS is 60, the maximum and minimum accumulation over the 30-year period is 110 and 2, respectively. The standard deviation for that week is 27.7. The table shows that there is a 90% chance of receiving at most 94 units, and, reading from the bottom, a 90% chance of receiving at least 27 units.

The tables can also be used to assess the accumulated amounts of heat units for given time periods through the growing season at stated levels of probability by summing within columns. For example, Table 39 can be used to find that at most 992 units accumulate by the end of June at Canton, MS at the 50% probability level. For that same time period, the table shows that at most 1,225 units can be expected 90% of the time.

Water Temperature

With the rapid expansion of commercial aquaculture in the state in recent years, the need for a climatological data base of water temperatures is apparent. A 36-year record of pond water temperatures has been derived by establishing a relationship between existing air and water temperature records (Wax et al., 1987). Figure 20 shows the daily average morning and afternoon pond temperatures (°F) at Stoneville, MS as derived from the predictive model. The figure shows that afternoon pond temperatures average above 60 °F for about 9 months, and that morning pond temperatures average above 60 °F for about 8 months each year. The figure also shows that average pond temperatures do not exceed 88 °F nor fall below 47 °F.

Water Balance

Evaluation of the daily amounts of water added to landscapes by precipitation and lost from landscapes by evaporation provides an accounting of moisture fluctuations resulting from climatic processes. Such a water balance approach has been used to assess the impact of climatic variability on pond surfaces seasonally, annually, and spatially (Pote and Wax, 1988; Wax and Pote, 1990). The results of this method can also be used to reveal the important interplay between precipitation and evaporation that characterizes the drying potential, field work potential, and wet-dry periods on a daily basis across the state.

Figures 21, 22, and 23 show results of a daily comparison of precipitation (P) and evaporation (E) at Fairhope, AL, Stoneville, MS, and Stuttgart, AR for the period 1962-1986. These sites were chosen to illustrate the coastal-to-inland gradient in the water balance existing across the state. For each day, loss of moisture by evaporation and gain of moisture by precipitation were computed and cumulatively summed through the period. Cumulative patterns of P-E for the average year, the wettest year, and the driest year of the 26-year period were graphed for each location.

Comparison of results at the different locations documents the potential for precipitation to exceed

evaporation on a cumulative basis through the year across the state, and illustrates the differing and sometimes extreme amounts of climatic variability experienced in the state on a day-to-day and an annual basis. For example, the cumulative curve of the average year at each site shows that P exceeds E all year in the coastal environment (Fairhope), but that E begins to exceed P in the central (Stoneville) and northern (Stuttgart) parts of the state about the first of August and the middle of July, respectively. The figures also show that there are years when either P or E can dominate, on a cumulative daily basis through an entire year at all locations because P-E is consistently positive or negative.

Crop Water Demand

Quantifying crop water demand involves two steps: (1) estimating potential evapotranspiration (PE) to represent the demand of the atmosphere for water; and (2) modifying the PE by use of crop coefficients to account for the physiological demand of different crops at different phenoloical stages. Pote and Wax (1986) calculated crop water demand for five Mississippi crops using measured pan evaporation modified by a correction coefficient of 0.8 and further modified by crop coefficients as established by U.S. Department of Agriculture (SCS, 1970). Table 47 presents the water demands of those crops on a weekly basis throughout their growing seasons in Mississippi based on their emergence dates.

Data Not Included

This document has been prepared in response to the many requests for weather and climate information directed to MAFES scientists and the State Climatologist. Many such requests are for data that do not exist or are not available at the time and space resolution needed. Wind, humidity, dew point temperatures, amount and types of cloud cover, and many other characteristics of the atmosphere are observed and archived for publication at only three sites in Mississippi – the first-order weather stations of the National Weather Service at Jackson, Meridian, and Tupelo. Hourly or shorter-period observations are likewise limited in the state.

Many observations of the above variables are made in the state by privately-owned weather stations, by networks associated with research projects, and by other public and private agencies. However, these data are not routinely stored in data sets and none are published. They are, therefore, effectively unavailable to the general public and have not been included in this document. It is anticipated that some of these presently unavailable data will become more routinely available in the future, but there is currently no good mechanism for storing, retrieving, quality controlling, and publishing these data.
